Title : Semiconductor Devices.

Orig Put : 60 let radio. M . Svyaz'izdat, 1951. 210.

Abstract : Survey article on the theory and technology of manufacture of semiconductor and semiconductor devices. The latest types of semiconductor devices such as the laminated transistor with electric-field control and the semiconductor tetrode are briefly described and mention is made of a germanium tetrode with photoelectric control. The accomplishments of Soviet scientists in the development and application of photocells and photoresistors to radio engineering and automation are mentioned. The advantages of the use of semiconductors in certain circuit are briefly examined.

OSTRUMOV, B. A.,

[Transactions of the] Conference on the Occasion of the SCV/10*-13-3-11/11
40th Anniversary of the Nizhniy-Novgorod Radio Laboratory imeni

V. I. Lenin (22-24 May, at Gor'kiy) (Radiotekhnika, 13-8, 71-9, 1958)

K. M. Kosikov reported in short on two important discoveries
of M. A. Bonch-Bruyevich in the field of the propagation of
radio waves (1932-1933).-

A. A. Pustolkors, B. A. Ostroumov, N. N. Izotov, and V. I. Ge
spoke about the Tver' radio station as well as of the Nizhniy-
Novgorod Radio Laboratory.

The participants in the conference visited the laboratory
establishments of the NIRFI at Gor'kiy State University where
they became acquainted with the observations made according to
the program of the International Geophysical Year.

Aboard the motor ship "Ukraina" by which the participants in
the conference sailed to Gor'kiy a readers' conference of the
periodical "Radiotekhnika" was held. It was arranged by the
Chief Editor M. R. Reznikov and the First Editor R.D.Mel'nikovs-
kaya. M. R. Reznikov spoke about the activity of the editorial
staff. Ya. M. Srin (Moscow) stressed the fact that the peri-
odical supplies only little information on the problems
turning up in industry. I. M. Kogan (Moscow) was of opinion
that more articles concerning applied theory should be dealt
with. A. V. Bogdanov (Leningrad) suggested to publish a special

size, excellent for metal ceramics. Ulitovskiy was assisted in his work by V.A. Shpirnov, S.D. Bogoslovskiy and staff of the Institut metallurgii imeni Baykova Akademii nauk SSSR (Institute of Metallurgy imeni Baykov at the Academy of Sciences of the USSR). Method II consisted in preparing the wire in a liquid state within a protective envelope of glass. Assisted by engineer Yu. V. Denisov, Ulitovskiy designed a micro-furnace using a high-frequency heater (30 kw/cm^2) capable of melting tungsten or molybdenum. A small piece of metal is placed in a glass tube and fitted in the heater. The metal melts and then melts the glass which can then be drawn out into a fine capillary containing molten metal. This is cooled by air or water into fine glass-insulated wire which is wound onto a spool. The thickness can be varied from 2 to 300 microns and more, with insulation 1 micron thick. With a diameter of 50-60 microns and less the wire and insulation is quite flexible, while above this diameter the brittleness of the glass coating can be offset by heating the wire to $400-600^\circ\text{C}$ before use, when the glass becomes quite plastic. The wire can be made of manganese, copper, bronze or iron. N.M. Averin has been successful in developing the technology of wire-drawing from these metals, and several wire-drawing devices have been designed. Ulitovskiy's apparatus, designed at the Institute of Metallurgy at the Academy of Sciences of the USSR, can be seen facing page 16, while a

Micrometallurgy

second device was exhibited at the 1959 Soviet Exhibition in New York. The super-fine wire has made possible the production of miniature transformers, relays and resistances, which can be sealed in glass under a high vacuum to improve their efficiency, reliability and independence from the external medium. Since the glass conducts heat away from the wire quite efficiently the wire can stand temperatures up to 600-800°C, making it useful in devices used in hot furnaces or in the chemical industry. Thanks to this, it can also withstand a 2-3-fold current overloading and is therefore useful in transformers for high-frequency equipment, giving a 4-5-fold saving in size and a 100-fold saving in weight. Using the wire, engineer D.V. Timashev has increased the sensitivity of mirror galvanometers to weak currents 1,000-fold, while Candidate of Technical Sciences B.K. Zavarikhin has designed a galvanometer with a damping period of 0.01 sec, leading to the development of simple and cheap electrocardiographs. The wire gives even, good-quality windings with little danger of a breakdown in insulation. If the winding or coil is heated steadily at 400-600°C, the glass insulation fuses into a homogeneous, well-insulated structure with no need for a form or carcass.

There are 4 sets of diagrams. X

"Separation of Boron from Aluminum and Iron. E. A. Ostroumov
(Kadis' Metalli (Rare Metals), 1933, 2, (5), 25-29). (In Russian.) After the
separation of SiO_2 and sulphides the solution is boiled and Fe^{2+} is oxidized
with bromine. After neutralization with Na_2CO_3 , a few drops of HCl are added,
and Al and Fe are precipitated with a 3% solution of tannin in a saturated solu-
tion of CH_3COONa . The solution to be analyzed must be added to the
boiling solution of tannin. The filtrate is evaporated with HNO_3 until it
clears and Be(OH)_3 is precipitated with NH_4OH . D. N. S.

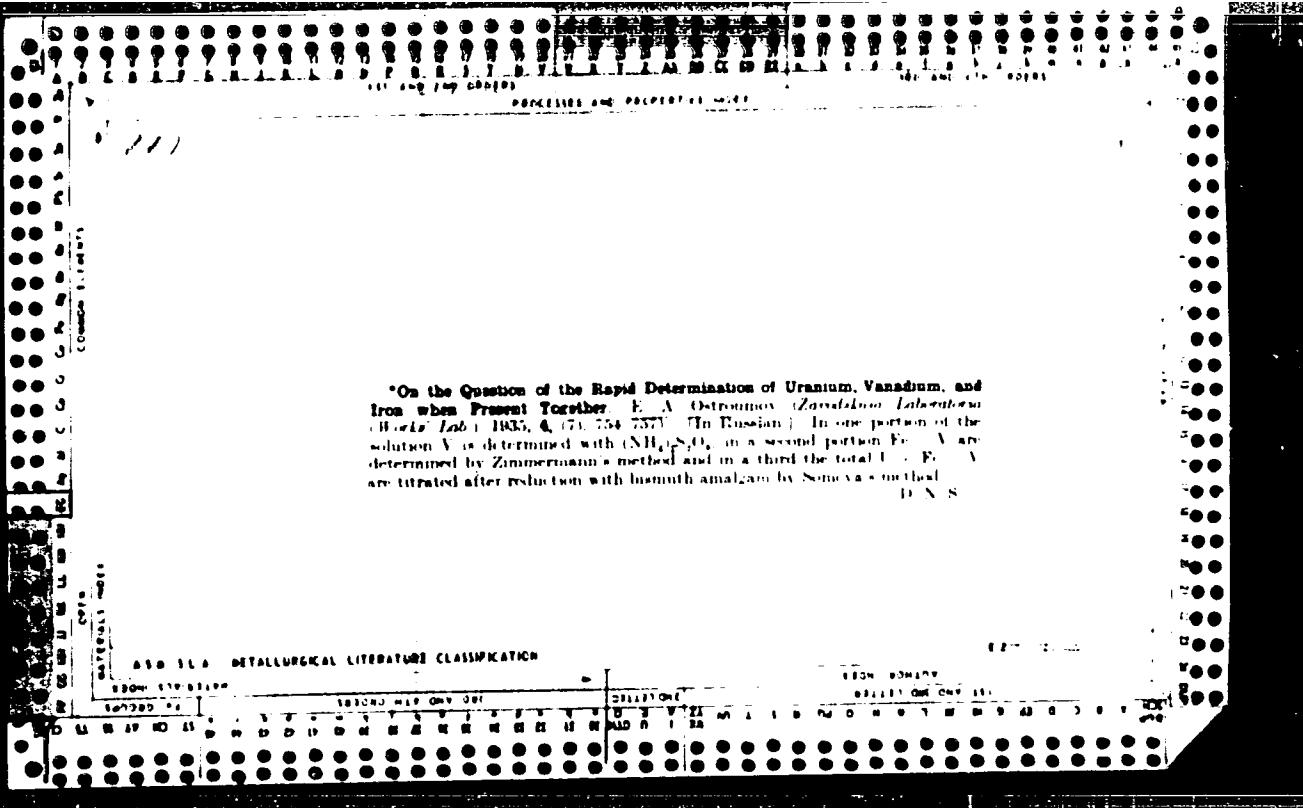

Determination of minute quantities of vanadium in
uranium preparations N. I. Chervyakov and R. A.
Ostrovskiy Zavodskoy Lab. 3. 1971 (1974) The
USSR

The colorimetric determination of V is based on the reaction of V with Hg(II) in
the form of the Hg(II) salt of $\text{p-HgSvCl}_3\text{Me}_2$. To facilitate the formation of
Wurster red, a similar color reaction is obtained with
 $\text{p-C}_6\text{H}_4\text{NH}_2$, Katakuzinov, et al. [26, 27].
The color, fugitive in H_2O , is stabilized with a large excess
of $\text{p-C}_6\text{H}_4\text{NH}_2$. The salts give a similar color reaction and are con-
verted into more stable complex compounds with glycerol and
 H_2PO_4^- . V was determined in an artificial matrix of 0.1 g of
uranium, 0.00012 g of UO₂ with an accuracy of
approximately 5%, or better. Dissolve 0.2-0.3 g of each
(or UO_2), of nitrate or acetate must be converted into
the chloride or sulfate in 10 ml H_2O , add 5-6 drops of 0.1%
Hg(II) salt, 0.5 cc H_2PO_4^- (or more), 1.4 cc glycerol,
1 cc $\text{p-C}_6\text{H}_4\text{NH}_2$ (or more), add 1 cc
to dissolve any turbidity with a min. of HCl, add 1 cc
of 0.5% I and compare with the standard soln prepared
the same way with c. p. VCl_3 by adding a titrated soln
of V(IV) until the 2 colors match.

The nature of the selenium compounds in the anode sludges in electrolytic copper refining. B. A. Strumov. Zernitskaya Lab. 3, 667-9 (1934). The total Se in the sludge was detd. by a method similar to that of Bruckner (1, 4, 20, 64%). The tests for free Se were made by extrn with CS₂ and oxidation with HNO₃. Selenites were detd. by extrg. the sludge with NH₄OH, pptg. Ag with HCl and repeatedly pptg. Se with Fe(OH)₃ (Brandell). The selenides were detd. in the extrn. residues from the preceding detn. by oxidation of Se with 50% HNO₃ to H₂SeO₃ and proceeding as above. The analysis showed that the sludge contains AgSe 6.12, CuSe 1.2, Ag₂Se 0.87% and no free Se.

Separation of calcium from strontium and barium

"On the Separation of Bismuth from Lead and Copper. E. A. Ostroumov
Zavodskaya Laboratoriya (Nauka) Zash., 1935, 4, (9), 1016-1020. [In Russian.]
The following methods for separating Bi from Pb were studied with synthetic mixtures: (1) hydrolysis of the Bi salt with (a) KBrO₃ and KBr, (b) HCO₃Na;
(2) precipitation with pyrogallol; (3) precipitation with cupferron. Method
(a) was the most reliable and method (b) the least satisfactory. Method
(c) can also be used for separating Bi from Cu; good results are also obtained
by converting the Cu into a cyanide complex and precipitating the Bi with
alkali. The basic carbonate method is unsatisfactory. D. N. S."

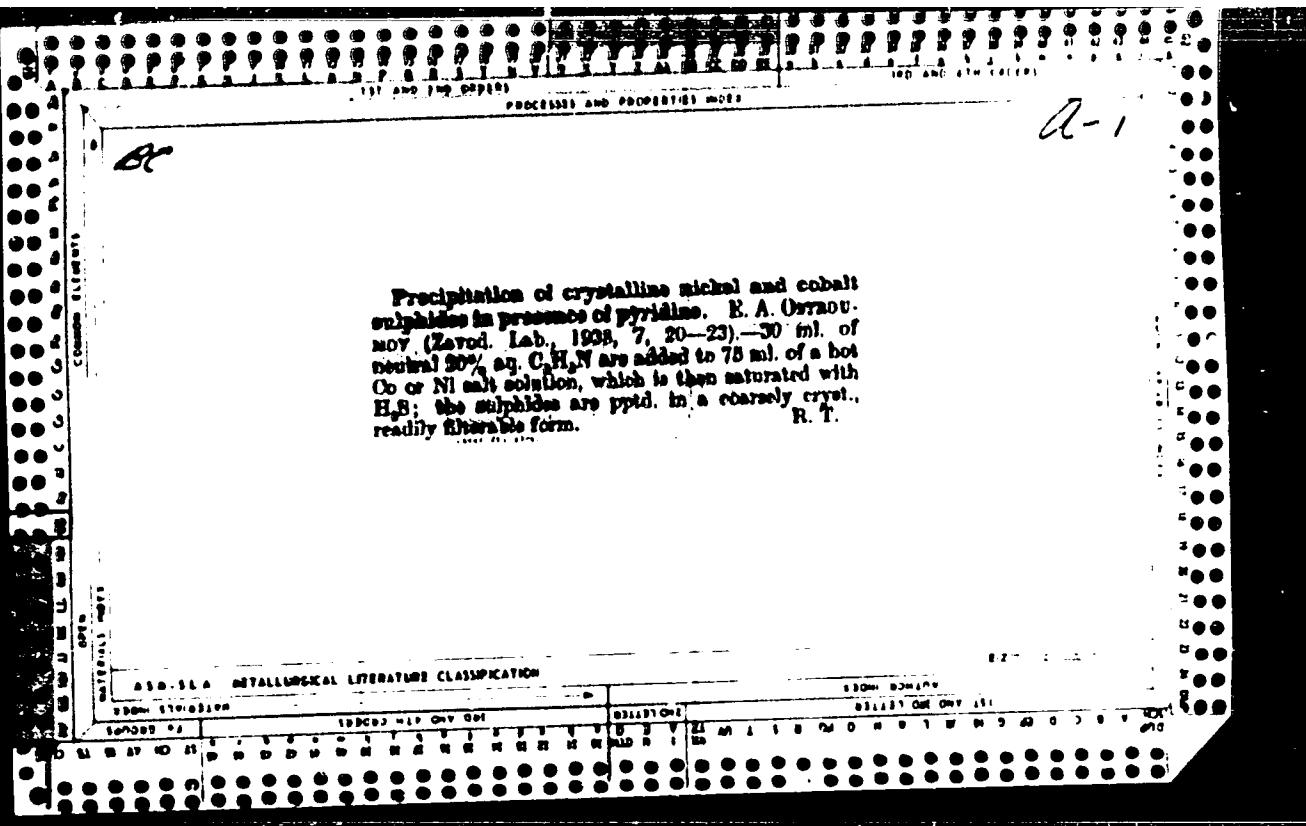

APPENDIX METALLURGICAL LITERATURE CLASSIFICATION

Separation of small amounts of tin from arsenic and antimony. N. I. Tsvetavskiy and E. A. Ossrovskiy (Zavod. Lab., 1938, 5, 1173-1176).
—The acidic solution, containing tartaric acid and group IV and V cations, is made neutral with NaOH, and poured into hot 4% aq. Na₂S, and the solution is filtered from group IV sulphides. As, Sb, and Sn sulphides are ppt'd. from the acidified filtrate. The washed ppt. suspended in 80-100 ml. of H₂O₂, is dissolved by adding 2 g. of KOH per 0.1 g. of As + Sb + Sn. H₂O₂ (1 ml. > required to oxidise the sulphides) is added, and the solution is boiled for 15 min. M-cresol is added, followed by HCl to a red colour, after which 8 ml. of conc. HCl are added per 100 ml. of solution. Excess of 5% aq. cupferron is added to the solution at 3-5°, the ppt. is collected, washed with 0.03% cupferron at 3°, ignited with HNO₃, and weighed. Good results are obtained for 0.3-30 mg. of Sn, in presence of considerably greater amounts of Sb and As. R. T.

Separation of iron, aluminum, chromium, uranium, zirconium and titanium from manganese, cobalt, nickel, magnesium, alkaline earth metals and alkalies by means of pyridine. A. Ostromowicz, Zosd-konf. ZAK 6, 1960, p. 30-34W. In the quantitative separation of Fe, Cr, Al, Ti, Zr and Ti with excess pyridine, the hydrolysis of Zr and Ti with the formation of highly dispersed basic salts is eliminated in the presence of excess NH₄Cl for every 100 g. of the salt. In the procedure affairs a good sepn. from Al, Cr, Ni, all earth metals and alkalies.

7

Methods for separating zinc from cobalt, nickel and manganese with hydrogen sulfide and determining zinc as zinc anthranilate. I. A. Ostryakov. Zavodskaya Lab. 6, 1958-64, 1957. C. A. 1-31, 5714. The best results were obtained in the sepn. of Zn from Co, Ni and Mn with H₂S by the Oakwell and Moyer method (A 30, 1961), but with the use of 5 ml. of the acrolein soln. and the omission of gelatin, and in the detn. of Zn as Zn anthranilate by the Funk and Ditt method. C. A. 27, 1962. Chas. Blatt

16

Separation of cobalt and nickel from manganese. 1
A. Ostromirov and G. S. Mademinskaya. Zavodskaya Lab.
7, 267 (1988) (U.S.S.R.). In the modified
procedure Co and Ni can be completely separated from Mn by
boiling with H₂S in the presence of pyridine-HCl instead of
pyridine alone. A neutral or slightly acid solution (2%)
is treated with the soln. of pyridine-HCl (1 ml of concd
HCl in 20.5 ml H₂O) neutralized with pyridine to methyl
acetate. The hot soln. is then treated with 1.1 ml of 5%
pyridine and a H₂S current for 10-15 min. The crystallized
CoS and NiS are filtered from the soln. Mn-pyridine complex
and are dried as before. V. V. Blane

Precipitation of manganese in a crystalline state by hydrogen sulfide in the presence of hexamethylenetetramine. B. A. Ostromoy. Zavodskaya Lab. 7, 1243 (1938). If a slightly acid soln is treated with 2 g hexamethylenetetramine (or max 0.5 g Mn) and then the soln at 00° is added with H₂S, an orange-red ppt of MnS is obtained which is easily filterable. The MnS can be calcd and analyzed by any known method. Alkalies and alk. earths are detd in the filtrate from MnS. In the analysis of ores Co and Ni are ppred as sulfides with pyridine and H₂S (C. I. 32, 8080²) and the filtrate is used for detg. Mn after the pyridine is driven off. Chas. Blanc.

CH

Precipitation of uranium with hydrogen sulfide in the presence of an organic. I. A. Chernenko and R. I. Bannister, *Z. radioaktiv. Lsd.* 8, 558 (1959). Heat 100 ml. of nearly neutral UO_2Cl_4 soln. in a 250-ml. flask to 60°, add 2 g. of $(\text{C}_2\text{H}_5)_2\text{N}_2$, and pass in H_2S for 15 min., and then for 15–20 min. more with the flask on the hot plate. Shake frequently, cool, allow the ppt. to settle for 15 min., filter, wash with 0.5% NH_4NO_3 contg. 2–3 drops of NH_3 (20 ml.) and ignite to U_3O_8 . For a weighing of 1.00 g. in the sample the results showed 0.0091 g. of the red ppt. (UO_2)

is believed to be $\text{U}_3\text{O}_8 \cdot (\text{C}_2\text{H}_5)_2\text{N}_2$. This compound shows negligible adsorption. The reaction can be used to separate from UO_2Me_3 and alkyls with semiductory character. H. Z. Kamm

***Separation of Bismuth from Lead, Copper, and Cadmium with the Aid of Pyridine.** N. A. Ostromov (Zerod. Lab. (Works' Lab.), 1939, 8, 1226-1229, C. Abstr., 1940, 34, 6770).—[In Russian.] The separation is based on precipitation with a mixture of pyridine and its nitrate. Heat 100 ml. of the solution containing Bi, Cd, and Cu to about 100° C. and neutralize gradually with 10% NH₃. Then add concentrated HNO₃, dropwise until the solution is clear, add 6.4 grm. NH₄NO₃, heat to boiling, remove from burner, and while shaking add dropwise 20 ml. of the reagent, which is prepared by mixing 20 ml. of 6N HNO₃ or 15 ml. 8N-HNO₃ with 34 ml. pyridine, and diluting to 100 ml. Heat to boiling, allow to settle for 30-40 minutes, and filter without cooling. Wash the precipitate with a hot solution of 3% NH₄NO₃ containing 1% by volume of the precipitant. Dissolve the precipitate in hot 6N-HNO₃, diluted with an equal amount of water, collect in a 1/4 cup and evaporate to dryness on a water bath. Moisten the residue with 1-2 ml. water, add 8-10 drops of 10% NH₃, and evaporate to dryness. Repeat this process so that the pyridine is completely removed. Ignite gradually and weigh as Bi₂O₃. If less than 0.1 grm. Pb is present it is not necessary to reprecipitate the Bi. The method gives good results.

New method for separating some of the third group from calcium, magnesium and alkali ions by means of hydroxyl sulphide in the presence of hexamethylenebis-tetramine
F. A. Ovchinnikov and R. I. Romashkin Zondishnoe Lab. No. 130-12 (1949) — This paper is based on the pptn. of vanadate in the presence of $(CH_3)_6N_2$ in a soln. of gradually increasing pH. The sample should contain not over 0.5-0.8 g. of the third group elements calcd as oxides. Add 20-25 g. NH₄Cl, neutralize with NH₃ to cloudiness, dissolve the ppt. with a few drops of HCl, and dil. to 150 ml. Add macerated paper pulp, heat to 60°, add dropwise, while shaking, 6 ml. of pyridine hydrochloride, and introduce H₂S. After 10-15 min. add dropwise, while shaking, 35 ml. of a 20% $(CH_3)_6N_2$ soln., transfer to a hot plate, and continue passing in H₂S for 45-60 min. without boiling. Remove from the hot plate and pass in H₂S until the soln. has cooled to room temp. Filter and wash with slightly ammoniacal 3% NH₄NO₃. Acidify the filtrate with HNO₃, to methyl red and evap. to 20-22 ml. Destroy the org. matter with HNO₃, dil. with water and det. the Ca and Mg in the usual manner. Det. the alkalies as sulfates by evap. with H₂SO₄ after the org. compds. have been destroyed. The method is useful for the analysis of Mn ores and similar products. B / K

New method of precipitating metal sulfides with aqueous hydrogen polysulfide. B. A. Gerasimov and G. S. Alatinkova. Zneshch. Lab. 9, 340 (1949). Add 5 ml of H₂S (1/2) to each 100 ml of chloride or sulfate solution of the metals, some filter paper pulp, and of H₂S polysulfide stopper and shake strongly. Remove the copper from an elec. plate with frequent shaking without bringing to boiling. Filter, wash with cold water and separate the metals by the usual methods. The precipitation of quinquevalent As is very slow and it is preferably reduced to three-valent state with SO₂. In the presence of Mo it is advisable to make the soln more acid and to increase the length of heating to 1.5-2 hrs. After the separation of the sulfide of Mo the soln should be added to precipitate the other sulfides. The sulfides thus obtained can be washed with distilled water.

The chemistry of lanthanides. I. The pH value in the precipitation of lanthanum hydroxide. B. N. Ivanov-Smol'yanov and E. A. Olsenevskaya. *J. Gen. Chem. U.S.S.R.* 16, 777-802 (1946) (English summary).—Curves are presented showing changes in pH, d.d.t., with indicators (cf. C.A. 31, 6860), and formation of pptn. on addition of 0.1 N NaOH to 0.005 M LaCl_3 (I) and 0.0005 M $\text{La}(\text{SO}_4)_2$ (II) soln. to 0.005 M NaOH . With I, pptn. begins at pH 3.70 with 0.6 eqv. of NaOH and is complete at pH 6.80-6.85 with 2.7-2.8 eqv. of NaOH. With II, these data do not indicate formation of a basic ppt. of $\text{La}(\text{SO}_4)_2$ until after adding 2.0 equiv. of NaOH; the pH is 7.80-7.90. With II, 2.0 equiv. of NaOH, the pH is 7.80-7.90. With II, 2.0 equiv. of NaOH, the pH is 7.80-7.90 with 0.86 equiv. of NaOH, which corresponds approx. to formation of the ppt. $\text{La}_2\text{O}_3(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$ as was confirmed by analysis of the ppt. With II, pH 7.1 is reached on adding 3.0 equiv. of NaOH. The close similarity between the behavior of La and Al salts toward NaOH is pointed out. J. W. P.

Separation of iron, aluminum, and chromium from zinc by means of pyridine. I. A. Ostrogomov and R. I. Gerasimova. Zavodskoye Lab. 11, 146 (1955). It was found possible to effect a satisfactory separation of Fe from Zn by a double pptn. of Fe(OH)_3 in a soln. made basic by addition of the dropswise addition of pyridine to the boiling bath, nearly neutral soln. In the filtrate the Zn was pptd. as a Zn pyridine complex. A $\text{CrCl}_3\text{-ZnCl}_2$ melt followed with NaOH . The ZnS ppt. was ignited to oxide and the Zn dotted as anthranilate. Somewhat less satisfactory results were obtained in the same way from a soln. conta. $\text{Al}_2\text{Si}_2\text{O}_5$ and ZnCl_2 , but in the case of $\text{CrCl}_3 + \text{ZnCl}_2$ the results were unsatisfactory unless the boiling soln. contained about 20% of NaCl . 22 references. W. J. Henn.

Reported and corrected by
Analysis of anhydrous aluminum chloride h. A.
Ostrovskiy and B. N. Ivanov-Koum. Zavodskaya Lab. 11,
279 AC(1943). To prep. a sample for analysis, take 17 g
of AlCl₃ and hydrate carefully by adding 30 ml. of concentrated
HNO₃ + water to make one l. After 24 hrs. repeat this
treatment and in 48 hrs. the sample should be all dis-
solved. Of the mixed salts, take 30 ml. and ppt. Fe(OH)₃ with the usual precautions by NH₄OH in the pres-
ence of NH₄Cl. Dissolve the Fe(OH)₃ ppt. in HCl and
titrate the Fe by the Zimmermann-Krumboldt procedure
(if less than 0.3% Fe is present, the colorimetric determination with
maltonic acid is preferred). To det. Ti, first remove
any silicic acid, by the usual evapn. method, filter, wash
with hot, dil. HCl and ppt. the Al, Fe, and Ti with NH₄OH
as hydrated oxides. Fuse the ignited ppt. with K₂Na₃C₆H₅O₂
and in the dil. H₂SO₄, eat. of the melt det. Ti with H₂AsO₄
Calc. the Al content from the wt. of the Fe(OH) + Al(OH)₃ +
Ti(OH)₃ ppt. after deducting the Fe and Al contents. Det
Cl⁻ in the original salts by the Volhard titration after
adding excess AgNO₃ and filtering off the AgCl. A method
for detg. the quantity of hydrated AlCl₃ and suitable app.
are described. The procedure is based on the fact that the
anhyd. AlCl₃ is completely volatilized by heating in a
current of dry air at 200-300° but the hydrated chloride
forms a basic salt on being heated, and is not volatilized.

Procurement of beryllium hydroxide by means of α -picoline. P. A. Ostromnev and B. N. Ivanov. Izv. Akad. Nauk SSSR, No. 10, p. 2200, 1945. The pptn of $\text{Be}(\text{OH})_2$ by means of α -picoline can be used for the quant sep of the Be from Mn, Co, Ni, and Zn (which form complexes with α -picoline), and from Ca, Sr, Ba, Mg, and bases. Neutralize 150 ml of the soln with NH_4OH (adding it dropwise with const stirring until a slight turbidity appears, which is removed by adding of 2-3 drops of 10% HCl), add 8 g. of NH_4Cl (in the presence of Zn the quantity of NH_4Cl added should be approx 0.15 g./ml.) and several drops of methyl red. Heat the soln to boiling, add dropwise with stirring enough of 20% α -picoline soln to change the color of the indicator to yellow, then 10-15 ml. more, cover the beaker with a watch glass, heat the soln to boiling, stand for the beaker in a water bath for approx 20-30 min., let part of the ppt. to settle and congeal, filter the soln while hot, wash the $\text{Be}(\text{OH})_2$ ppt. with hot 3% NH_4NO_3 , and a few drops of 20% α -picoline soln. It is used for a single pptn. In the presence of very large quantities of Zn, Mn, Co, and Ni, for a complete sep, dissolve the $\text{Be}(\text{OH})_2$ ppt. in 10% HCl and repeat the pptn as described. Dry the $\text{Be}(\text{OH})_2$ ppt., ignite it in a Pt crucible at 1000-1000°, cool, and weigh as BeO . The cations remaining in the filtrate can be sep by methods described previously. Three references. W. H. Hunt.

Separation of gallium hydroxide by pyridine. B. N. Ivanov-Kunn and E. A. Ostromov. Zerklobov Lab. 12, 674-8 (1940). Pyridine ppt's quantitatively Ga(OH)₃, which on heating loses part of its water, and is transformed into an almost insol' form. A small excess of pyridine and considerable amounts of NH₄ salts do not increase its solv' to any considerable degree. In the presence of salts of Mn, Co, Ni, Zn, Cd, and Cu, pyridine ppt's Ga(OH)₃ contaminated by these metals, owing to a partial formation of gallates, especially with Co, Zn, and Cd. In the presence of large amounts of NH₄Cl it is possible to separate pure Ga(OH)₃ in one pptn. The method can be used not only for analytical purposes, but also to prep. high-purity Ga compds. and to sep. Ga from alk. earth metals, Mg, and alk. metals. To an acid soln' of a Ga salt contg. Mn, Co, Ni, Zn, Cd, or Cu add with const. mixing dil. NH₄OH until a slight turbidity is formed, dissolve by adding several drops of dil. HCl, add approx. 15 g. of NH₄Cl, bring the vol. to 150 ml., add some macerated paper (flat to boiling, add methyl red indicator and 20% pyridine soln (dropwise with mixing) until the color changes to yellow, heat liquid with the ppt. to boiling, let stand for 1 hr. at a temp. close to boiling (owing to evapn. of pyridine the color of the soln. changes to red and therefore, during the pptn., pyridine soln. sufficient to change the color of the indicator should be added) filter, wash the pptn., dissolve in HCl, and measure the color produced with a suitable reagent (Mn with (NH₄)₂SeO₅, Co and Ni with dimethylglyoxime, Cu with pyridine). The pyridine chloride complexes of Zn and, thus, yancate.

especially, of Cd (general formula (MPy)_nCl_n) are slightly sol. in the cold, and therefore the liquid should be kept warm during the filtration and the pptn. washed with hot 2% NH₄NO₃. In the washed pptn. Zn and Cd are detd. spectroscopically. The sepn. of Ga from Zn and Cd is nearly complete that no reppn. is required. Addn. of NH₄NO₃ to the soln. also results in the formation of pyridine complexes of greater solv., and the sepn. of Ga from Zn and Cd is less nearly complete; complete sepn. requires reppn. The alk. earth metals and Mg form no gallates under the conditions of Ga(OH)₃ formation by pyridine, and they can be sepd. completely from Ga. Ga can be sepd. also from K, Na, and Li. W. R. Henn

Separation of thorium hydrosulfide by means of pyridine
E. A. Ostroumova and S. Beruchyan Zavodskaya Lab.
12, 302-77-0400 To the acidic soln add NH₄Cl or NH₄
NO₃, neutralize with NaOH until a slight permanent
turbidity is produced, dissolve this with a little HCl, heat
to boiling and add 2% pyridine soln until added methyl
red indicator soln turns yellow. The presence of SO₄
interferes owing to the formation of sol. double salts such
as NH₄ThSO₄, but this error is in some cases overcome
by adding considerable NH₄Cl. Pptn of Th(OH)₄ by
pyridine is often advantageous in separating Th from many
hydrogen sulfide.

Separation of cerium from rare earths by the bromate-pyridine method. A. Chitunayev. *J. Russ. Phys. Chem. Soc.*, Vol. 2, 1111-17 (1917). Ce can be separated quantitatively from other rare earths as a basic bromate in a soln. buffered with pyridine and pyridine-HCl. Evap. the soln. containing the rare earths to dryness. Dissolve the residue in 2.5 ml. of HCl, add approx. 100 ml. of hot H₂O, and 0.3 g. of NaOH₂O (to oxidize Ce²⁺), stir, cover with a watch glass, and boil carefully on a hot plate, adding hot H₂O from time to time as it evaps. Boil for 30-45 min., until the color of the vanishes. Remove from the hot plate, add 1 g. of NaOH₂O, mix, and repeat the slow boiling for approx. 1 hr. Remove from the hot plate, and after 3-4 min., add dropwise with stirring, 10 ml. of buffer soln. (21 ml. of 6 N HCl + 20 ml. water + 25 ml. of pyridine + 35 ml. of water). Let stand overnight, filter, and wash the ppt. with cold H₂O; basic Ce bromate is pptd. quantitatively. Treat the ppt. with 80 ml. of a hot, 10% oxalic acid soln., add 0.8-1.0 g. more of oxalic acid, and boil for 40-45 min. to complete the conversion of bromate to oxalate. Dil. the mist. to its original vol. and keep overnight. Filter, wash with dil. oxalic acid soln., ignite, and weigh as CeO₂. Excellent results were obtained. M. Hoch

Determination of pyritic sulfur in the presence of sulfides. A. V. Kostomy and W. S. Iverson. *Bureau of Mines, Report 2, 314-22 (1947)*. The purpose of this investigation was to test and improve the Hatch procedure (C. A. 13, 1570). The formation of free S can be prevented by carrying out the reaction in the presence of metallic Sn. The formation of big droplets is prevented by increasing the length of the neck of the reaction flask. The leaching effect of sulfides is prevented by the addition of BaSO₄. To det. FeS in gypsum, take 0.5 g. of sample and place it in a thimble of Sn foil. Moisten the solid in the thimble with BaSO₄ soln. and a little HClO₄ if necessary to wet the powder well. Place the thimble in the reaction flask and connect the flask to a condenser and to 2 receivers containing $\text{Cu}(\text{CH}_3\text{COO})_2$ soln. While introducing CO_2 into the app., add 50 ml. of HClO₄ through a dropping funnel in the neck of the flask, and 1.15 ml. of HgO . Heat very slowly at first but continue heating below the bp. for 3.4 hrs. Eventually boil 10 min. and allow to cool while continuing the stream of CO_2 . To the combined contents of the receivers add dropwise a 1% soln. of CuSO_4 in 2 N H_2SO_4 . Cool, filter off the CuS ppt., wash the ppt. to remove all Cu^{2+} ions and ignite to CuO in a porcelain crucible. To det. FeS in the presence of other sulfides, first carry out the above procedure with HClO₄ and no Sn. After the other sulfides have been removed, filter the soln. in the reaction flask and treat the residue as described.

C
Fundamentals of new analytical methods with pyridine,
 α -picoline, and hexamethylenetetramine. E. A. Ostroumoff
mos. Zemel'skaya Lab. 18, 604-10 (1947) — The methods
are based on the use of pyridine as a regulator of the pH
of acids, during hydrolysis and formation of complexes
in adding pyridine to a weakly acid solution, a pH of about
6.8 results when some metals are present as hydroxides while
Mn, Ni, Co, Zn, Cu, and Cd form easily and complexes
Pyridine solns. contg. pyridine nitrate will give a stable
pH of 4.1-4.2; under these conditions it is possible to sep
Bi from Pb (and also from Cu and Cd which form soln
complexes with pyridine) and some rare metals from tri-
valent Ce and rare earths. In reaction between α -picoline
and the acids, the isopropylidene, the resulting
pH is 7.0. Thus, Bi(OH)₃ can be sep'd from Ca, Sr, Ba,
Mg, and alkali. Two procedures are proposed. (1)
Remove the cations of the 3rd group with H₂S in the pres-
ence of hexamethylenetetramine. Destroy org. material
in the filtrate with HNO₃ and det. alk. earths, Mg, and
alkali as usual. Ash the sulfide ppt. of the 3rd group
quite carefully, and treat the ash with concd. HCl while
heating. If an insol. residue remains, filter, wash with water,
sep. Fe, Al, Cr, Ti, Zr, In, Ga, and some pyridine
metals from Mn, Zn, Ni, and Co. From the filtrate, after
the addition of pyridine hydrochloride, ppt. Co, Ni, and
Zn with H₂S, thus wrg. these from Mn. (2) Sep. Fe, Al,
Cr, In, Ga, Ti, Zr, and some rare metals with pyridine.

From the filtrate, after the addition of pyridine hydrochloride,
ppt. Ni, Co, and Zn with H₂S. From the filtrate, after
the elimination of the pyridine ppt. Mn with H₂S in the
presence of hexamethylenetetramine. In the filtrate
from Mn, after the destruction of the org. material with
HNO₃, det. the alk. earths, Mg, and alkali as usual. (1)
is preferred when Ca, Mg, and alkali are det'd in products
contg. large amounts of Mn, Co, and Ni. This procedure contains
considerable phosphate and small quantities of Al, Ti, and
Zr, because then some of the Ca may be ppt'd as phosphate.
But if the Al, Ti, and Zr are sufficient to combine with all
PO₄, then the method is applicable. (2), with sufficient
Fe⁺⁺⁺ in the soln., is also suitable when P and V are
present. In sep. Zn from Ni and Cu if it is preferred to
ppt. Zn with H₂S from a soln. contg. CH₃COCH₂OH and
Na(Ac). Rare earths should be sep'd as oxalates and then
pyridine and its nitric acid salt. If the product contains
Be, it is necessary to use α -picoline for complete ppt'n.
In the 4th group it is possible to sep. Bi from Pb, Cu, and
Cd with pyridine in presence of its nitric acid salt

100-114 METALLURGICAL LITERATURE CLASSIFICATION

Separation of scandium with the aid of pyridine. N. A. Olsina - Sov. (All Union Inst. of Mineral Raw Materials; Moscow) Zhur. Akad. Nauk SSSR, 1948, No. 11 (1948). - A method for sepr. Sc from other rare earths is based on the difference in pH at which their hydroxides ppt. Thus, the Sc(OH)₃ ppts at pH 4.9 (C. I. 30, 5132) whereas the hydroxides of other rare earths start ppts. at pH 6.3 (Yb and Lu) and higher. The desired pH is attained with buffer solns of pyridine or its salts (C. I. 34, 5779). To prep. the pptg. soln., measure into a 50-ml. flask enough concd. HNO₃, free of N oxides, and standardised, to correspond to 27.2 g. of 100% HNO₃. Add approx. 20 ml. of H₂O, mix, and add slowly 130 ml. of pure pyridine with const. shaking and cooling. When the soln. is at room temp., fill to the mark and mix thoroughly. To det. Sc, dissolve the sample, add approx. 5 g. of NH₄NO₃, carefully neutralize with dil. NH₄OH until a slight permanent turbidity appears, and then add 3 drops of concd. HNO₃ to dissolve it. Dil. to definite vol. (e.g. 100 ml.) and bring to a boil. Add a little macerated paper pulp and then from a dropping funnel add approx. 15 ml. of the pptg. soln. with const. stirring. Cover the beaker, bring to incipient boiling, and keep on a water bath for 40-50 min. to complete coagulation and ppts. of Sc(OH)₃. Filter, wash with hot 3% soln. of NH₄NO₃ contg. a small quantity of the pptg. soln. (5 ml. per 100 ml. of 3% NH₄NO₃), place the ppt. in a weighed porcelain crucible, dry, ash, ignite at 1000-1010°C, cool, and weigh. For 12 analyses in which ScO₂ was taken as 0.0001 g., there was no difference between "taken" and "found" in 6 cases, and in the other 6 analyses the difference did not exceed ±0.001 g. The filtrates were evapd. to a small vol. and tested for Sc - none was found. It is thought that Sc(OH)₃NO₃ is first formed, which upon addition of more pptg. soln. changes completely to Sc(OH)₃. Tests were run on sepr. Sc by this method in the presence of other rare earths severally and combined. The contamination

except for Gd, Ho, and Yb, where for the greatest accuracy, triple ppts. was needed. Similar results were obtained when the rare earths were taken together with Sc ratios of 1:1-1:4.

Determination of zirconium with mandelic acid. A. A. Astanina and B. A. Ostroumov (Inst. of Mineral Raw Materials, Moscow, USSR). Zhur. Anal. Khim. 6, 27 (1951). The purpose of this investigation was to check the Kunkins method (C. J. 41, 4736). The method was accurate and effective in sepn. of Zr from other metals including the rare earths and Mo. Equally good results were obtained by weighing Zr mandelate without igniting the ppt to ZrO_3 . The excess mandelic acid was removed by washing the ppt 2-3 times with KOH . Zr in quantities below 0.010 g. does not ppt. at once, particularly in the presence of other elements. In such cases the time allowed for pptn should be extended to 1 or more days. M. Husek

Rare earths in the deep water deposits of the Black Sea.
E.N. A. Ostromov. Doklady Akad. Nauk S.S.R. R. 1175-8 (1957).—Sediments from deep water regions of the eastern part of the Black Sea and the heavy mineral fraction from the sand on the Caucasian coast at Cegra were analyzed for La_2O_3 , CeO_3 , Pr_2O_3 , Nd_2O_3 , Gd_2O_3 , and Dy_2O_3 by the method of Borzenko-Staryakovich, et al. (C.A. 58, 20194). They were also detd. by an x-ray method. The predominant element was Ce. Most abundant in rare earths are the clayey muds. Those sediments contain all REEs and carbonate veins contain less of these earths. The quantities of these earths in the various sediments are tabulated.

Iron in the bottom sediments of the Okhotsk Sea. [E.A.
Ostrovomov.] Doklady Akad. Nauk S.S.R. 102, 129-32
(1955).—Fe (ferrous and ferric oxides) was determined in samples
from more than 200 regions of the Okhotsk Sea sediments.
The deposits are divided into 7 zones with Fe content from
1.0 to 7%. The zone with more than 7% of Fe occurs near
the Kuril Islands and in the south extremity of the Kam-
chatka shore. Most of the Fe comes to the sea from ter-
restrial materials and volcanic breakdown products. Some col-
loidal Fe is very fine suspension concentrates in the clay
slime together with Fe bound with the phytoplankton re-
sidue. In the south the concn. of Fe is associated with the
clay-diatom slime. Another part of the Fe, bound with
the volcanic activity products, concentrates in the sand and
silt particles, located along the Kuril Islands and the east

shore of Kamchatka. In comparison with other Russian
seas, sediments of the Okhotsk Sea have a high content of
Fe, which in some places amounts to 11.11%. A map of
distribution of Fe by zones is included. M.C.

Abstract: Process of reduction (R) of SO_4^{2-} in sediments takes place at definite strata and begins after R of Fe^{2+} in bed at definite stage of decomposition of organic matter necessary for life processes of sulfate-reducing microorganisms. R of SO_4^{2-} is well developed in sediments of Kuril-Kamchatka and Aleutian troughs where it begins in 10-15 cm strata; amounts of FeS reach 0.39% and free H_2S is present. East side of trough R zone is located below layer of sand and contains little FeS. In the sediment bed this zone is located in 150-200 cm layer

TITLE: Determination of Thiosulphates in Silt Waters of the Black Sea Deposits (Opredeleniye tiosul'fatov v ilovykh vodakh osadkov Chernogo morya)

PERIODICAL: Doklady Akademii Nauk SSSR, 1957, Vol. 114, Nr 4, pp. 853-855 (USSR)

ABSTRACT: In order to get a better idea of the diagenesis processes it is necessary when studying the types of sulphur compounds in sea deposits, not only to investigate the solid phase, but to determine also the types of sulfur compounds of the water by which these deposits are drenched. In the Black Sea, in which an intensive reduction process of the sulphates takes place, there may also occur sulphites and thiosulphates, besides free hydrogen sulfide and sulphates. The authors investigated, from the expedition ship "Akademik S. Vavilov", at the below mentioned station, whether these soluble compounds occur in the silt waters of the deposits. A method for the determination of sulfites and thiosulfates in the presence of free hydrogen sulfide had been previously worked out by Kurtenacker. Its applicability to the Black Sea was to be checked. The shallow-water deposits here often do not contain any hydrogen sulfide. In

Card 1/3

Determination of Thiosulphates in Silt Waters of the Black Sea Deposits 20-114-4-47/63

the silt water of the deep-sea deposits it is often removed during filtration in vacuum. Tests indicated that the content values of the thiosulfates obtained on this occasion are unstable and vary considerably. This is due to the leaking through into the filtration of small amounts of colloidal sulphurous iron (hydrotoilite). For that reason treatment with zinccarbonate suspension is indispensable. It removes the free hydrogen sulfide and the colloidal iron which is disturbing in the determination of the thiosulfates. The experiments showed that the silt waters in the Black Sea deposits contain virtually no sulfites, at the most very minute traces of them, whose amount lies within the limits of experimental errors. But steady figures for the thiosulfates are obtained in spite of their small amounts. They vary between from 0,0 to 10 mg/lit. The deep-sea deposits are richer in them than those of the shallow water. As is well-known one sulfur atom of the thiosulfates is very mobile and capable of reaction. Therefore the thiosulfates can function as a peculiar type of sulfur transmitters. In this respect the occurrence of thiosulfates may be of great interest in the study of diagenetical transformation of the Black Sea deposits. There are 1 table and

TITLE: Concretions of Iron Sulfide in Black Sea Deposits. A Note
sulfidniye zmeinye v otlozheniyakh Chernogo morya

PERIODICAL: Lektsiiy Akad. SSSR, 1957, V. 1, No. 1, 64-67, USSR

ABSTRACT: Already in the middle of the 19th century the Black Sea deposits and the possibility of a formation of pyritous concretions in it in form of tiny pellets was assumed. However, it was not until 1954 that concretions of pyrite of a length of 1 cm and a width of 1,5 mm were found there for the first time. Besides, 90,84% pyrites may consist of a small quantity of siliicate which apparently are of the deposit itself. A further review shows the presence of mel'nicovit, hydrotalcite, and marcasite also in the old Black Sea deposits. Transitions between the latter minerals occur, too. The research of these transitions and of the process could throw a light on one of the questions of the autogenous mineral formation of the bottom of the sea. In summer 1956 a pillar of the ground of a length of 1 m was taken in a depth of 140 m by the expedition ship, "Akademik S. Vavilov" from one of the stations beside the Cape Kaliakra ($42^{\circ}54'$, north latitude, $40^{\circ}41',8$ east longitude). It was grayish mud, grey, occurring with bluish tinge and with single intercalations.

Card 1/2

cc-32/51

Concretions of Iron Sulphide in Black Sea Deposits.

te layers and strings covered black by hydraterrile. The analysis carried out showed that the concretions consist mainly of iron sulphide. The latter contains considerable quantities of iron sulphide which can be decomposed by water either as pyrite, apparently mel'nicovit, and small quantities of pyrites, marcasite. Apparently the accumulations of colloidal hydraterrile form change into smectite, montmorillonite. In the case of a transition, the dehydration and condensation begins, as it can be assumed, the addition of the second sulphur atom under formation of the metastable form of iron sulphide-mel'nicovit which, in the further coarse changes into marcasite and pyrites. Thus it can be assumed with a certain degree of conviction that the found concretions are a transition form in the transformation of hydraterrile into pyrites, marcasite. There are 1 figure, and 11 references, 1 of which are Service.

ABSTRACT: The research work done during 1957-58 by V. I. Petelin and the ship "Vityaz" has proved that a special feature must be noted in the distribution of the Krasik waters. This consists in the fact that the author of this article found his research in the series of papers by V. V. Slobodkin and V. M. Vinogradov that the waters contain about 1% iron on the average. V. I. Petelin established that the contents of iron in the Krasik waters are much higher than the contents in the rivers adjoining the Krasik basin and that the figures 1 and 2, the maximum being 10 ppm, of iron which has been found in the Krasik River, are far from the figures various Soviet scientists who have taken samples in this field, such as A. N. Savchenko, V. G. Savchenko, O. Liverovskiy and V. M. Vinogradov and he believes that it is possible that the basic mass of iron enters into the Krasik basin through sediments together with sand, melting icebergs or the ice

Some peculiarities in the distribution of iron in the sediments of the sea
of Okhotsk

and of erosion products of the dry and subaqueous land
and of products of recent volcanic activity. The concentration
of the main iron-containing minerals in the subaqueous
clastic material, and the distribution of these minerals
according to the granulometric spectrum determines the
character of the iron distribution in the sediments of the
Okhotsk sea. Therefore, as far as the distribution of iron is
concerned, the Okhotsk sea can be regarded as a special type of
sea basin - a basin with talus-like types of distribution
of iron in the coastal zones.

Separation of amines from aldehydes
of Pyridine and Pyrazine.

Pyridine and Pyrazine are separated by the following method. A solution of 10 g. of aluminum chloride in 10 ml. of benzene is added dropwise to a mixture of 10 g. of the amine and 10 ml. of benzene. After the addition is completed, the reaction mixture is heated to 100° C. for 15 minutes. The precipitated aluminum hydroxide is removed by filtration. The filtrate is then concentrated and cooled to 0° C. The crystalline product is collected and washed with benzene. Recrystallization from methanol yields a white product. The yield is approximately 80%.

Card 2/3

Separation of Thorium from Rare Earths by Means
of Pyridine and Its Nitrate

precisely regulated in the precipitation and kept on a value of 4,1-4,2 by means of this solution. In the precipitation of thorium hydroxide it is desirable to add ammonium nitrate in order to accelerate the formation of a complete salt, and to accelerate the precipitation. It was proved that even in the case of a singular precipitation of thorium hydroxide by means of a mixture of pyridine and pyridine nitrate a practically complete separation of thorium from the rare earths can be obtained. Yttrium, lanthanum, trivalent cerium, neodymium, praseodymium, erbium, samarium, and ytterbium remain in the solution. Thorium is precipitated in the pure form that a re-precipitation is not necessary. The experimental carrying out of the separation is described very precisely. To receive figure, tables and 6 references, 1 of which are Soviet.

TITLE:

Determination of Sulfates by Their Reduction to Hydrogen
Sulfide (Opredeleniye sulfatov po sostanovleniyu ikhi do
serovodoroda).

PERIODICAL:

Zhurnal analiticheskoy khimii, 1971, vol. 16, No. 4, pp. 91-93
(USSR)

ABSTRACT:

Among the titrimetric methods for determining sulfates, those basing on a reduction of sulfate to hydrogen sulfide and a subsequent iodometric titration, are of particular interest (refs 1-11). In using titanium chloride and phosphorus oxychloride for the sulfate reduction (refs 7, 8), a disturbance is caused by copper and other elements of the same analytical group, which form sulfides difficult to solvate. The authors of the present paper worked out a method for determining sulfates. The reduction to hydrogen sulfide takes place with reagent obtained from SnCl_2 and phosphoric acid. With the fact that the apparatus for the reduction described by Fil'kin and collaborators (Ref. 8) has a number of defects, it was modified by the authors. The new apparatus is illustrated and described. It is characterized by the fact that it can be rapidly

Card 1/3

Determination of Sulfites by Their Reduction to
Hydrogen Sulfide

S.N. 7-174-17

reactivated and purified was obtained from the reaction of the concentrated phosphoric acid with tin chloride. This reagent was prepared in accordance with the directions given in the SnCl₄ with concentrated phosphoric acid until no precipitate of SnCl₂ was completely removed. In this connection it was found, however, that a reagent having a constant activity which is obtainable. Investigations carried out have shown that the fact that small amounts of chlorine remaining in the reagent after boiling not only do not disturb the sensitivity of the test but even intensify the latter. A prolonged heating of the reagent for the purpose of removing hydrochloric acid from it causes a considerable decrease in the reactivity, this being apparently caused by the formation of considerable amounts of concentrated phosphoric acid. A very accurate description is given in the preparation of the SnCl₄ with concentrated phosphoric acid, and also of the optimum as of the concentrated phosphoric acid, and also of the optimum conditions for the preparation of the reagent. Temperature is not increased beyond 50°. The reagent is diluted with water and stored. This method was tested on the following salts. As became apparent, the precision of analysis of pure salts. As became apparent, the precision of

Ca, Ba, Fe, Al, Cr, Mn, Co, Ni and Zn does not cause any disturbance. The reduction process is accelerated up to 10 times by the presence of alkali metals. Neither do K₂, Li and Cs disturb the reduction. Copper and mercury salts cause a disturbance. The same method was also adopted to analyze natural materials, as gypsum, Black Sea ooze and sea water. The results are on the same level with those obtained by the gravimetric determination of sulfate as BaS₄. A number of practical indications for this method is also given. There are 2 figures, 3 tables, and 11 references.

On the Question of the Formation of Hydroxy-scandiates of the
Alkali Metals (K voprosu ob obrazovanii hidroksoskandiata
shchelochnykh metallov)

PUBLISHER:

Zhurnal neorganicheskoy khimii, 1959, Vol 4, Nr 4, pp 727-731
(USSR)

ABSTRACT:

The separation of hexahydroxo-sodium scandiate having the composition $\text{Na}_2[\text{Sc}(\text{OH})_6] \cdot 2\text{H}_2\text{O}$, is described. For the synthesis of this compound scandium hydroxide produced by the method of N. A. Tananayev was dissolved by heating in 18 n sodium hydrate. The compound separated out was analyzed and the formula mentioned above was confirmed. The coordination number of scandium in this compound is 6. The crystalline compound has a rhombic lattice. The crystals frequently form druses. At a temperature of 25° the crystal density is $2.01 \cdot 10^3$ as measured by the micropyknometer by V. V. Syromyatnikov (Izaf 1957). The compound sodium hexahydroxo-scandiate decomposes on the effect of

PURPOSE: This book is intended for chemists, mineralogists and others interested
in the compositional analysis of minerals, rocks and sea-bottom deposits.
It may also be used by students and teachers in higher educational insti-
tutions to supplement textbook methods of chemical analysis.

COVERAGE: The book contains the accumulated materials on methods tested by the
Chemical Analysis Laboratory of the All-Union Scientific Research Institute
for Mineral Raw Materials (VIMS) which are used in the Chemical Analysis
Section of the Marine Deposits Laboratory attached to the Oceanology Institute,

3.	Precipitating uranium and separating from alkaline-earth metals	26
4.	Separation of uranium, zirconium and titanium from manganese, cobalt and nickel	32
5.	Separation of iron, aluminum, chromium, uranium, zirconium and titanium from manganese, cobalt, nickel, zinc, calcium, strontium, barium, magnesium and alkali metals	36
6.	Precipitating indium and separating it from manganese, zinc, cobalt, nickel, copper and cadmium	39
7.	Precipitating gallium and separating it from manganese, zinc, cobalt, nickel, copper and cadmium	46
8.	Precipitating thorium and separating it from manganese, nickel, zinc, copper, cadmium, alkaline-earth metals, magnesium and alkali metals	53
II.	Precipitation of Metals With Pyridine in the Presence of Its Salts	65
1.	Separation of bismuth from lead, copper and cadmium	65
2.	Separation of thorium from rare earths	69
3.	Separation of scandium from cerium and rare earths	75
III.	Precipitation of Metals with Hydrogen Sulfide in the Presence of Pyridine	82
1.	Precipitation of nickel and cobalt sulfides in crystalline form and

TITLE:

Forms of Sulphur Compounds in the Bottom Deposits of the Marian Depression (O formakh soyedineniy sery v donnykh otlozheniyakh Marianskoy vpadiny)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 126, Nr 2,
pp 385-388 (USSR)

ABSTRACT:

Although reductive process investigations are essential for better understanding of the diagenesis processes in the ocean-bottom sediments, such studies on the Pacific are seldom. With the beginning of the reductive reactions the direction of the diagenesis process and with it the character of the migration and the entire picture of the elemental re-distribution is changed. The reductive processes in the said sediments are caused by the life activity of the micro-organisms in the decomposition of organic substance. The sediments of deep-sea depressions are especially interesting owing to the fact that it is here that the organic substance collects. The reductive processes concern the tetravalent manganese and the trivalent iron in its free form (of the hydroxide type). Only then does the sulphate
